

HW 2 Challenges

The first challenge I have is that Ubuntu seems to support an outdated python system. After getting many syntax errors from executing the python file, I realized that and changed the shebang from `#!/usr/bin/env python` to `#!/usr/bin/env python3`, and the problem is solved.

The second challenge is to write the function that writes out train, development, and test text files while still maintain the format of the original text file. At first, the output file only have everything in one row. That's when I realized that I need to add `+"\n"` to get a new row for each iteration. The output file, though, does not have an empty row to break each sentence apart like the original text file does. Thus, I just iteratively append an empty list after each sentence list, so that there will be an empty row in the output text file after each sentence.
